

ERD for Soyuz's New Bookstore

Description for Customer Address Types

From an SQL design point of view, Customer Address Type1 and Customer Address Type2 represent two different strategies for handling changes to a customer's address.

Type 1 keeps only the current address by overwriting the previous one, so the table has a single row per customer and no historical tracking, making it simple, fast, however the past data will be lost.

Type 2, on the other hand, preserves every address change by inserting a new row each time the customer moves; it uses effective_start_key, effective_end_key, and is_current to mark the active address and maintain a full history. This makes Type2 ideal for analytics, auditing, and time based reporting, while Type 1 is better for operational systems that only need the latest address.
